Pumpkin Patch Scenarios

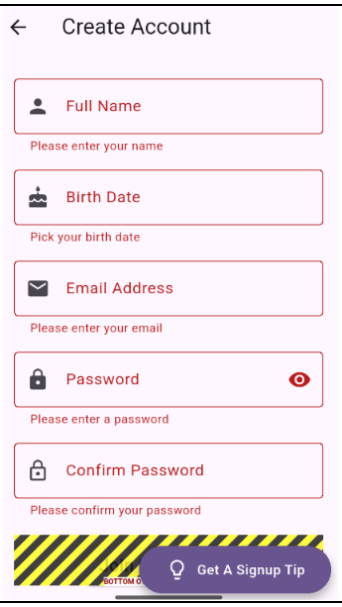

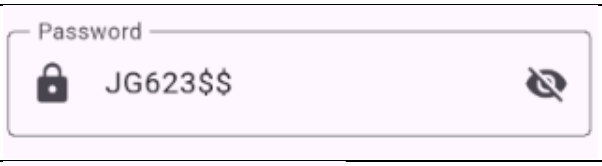

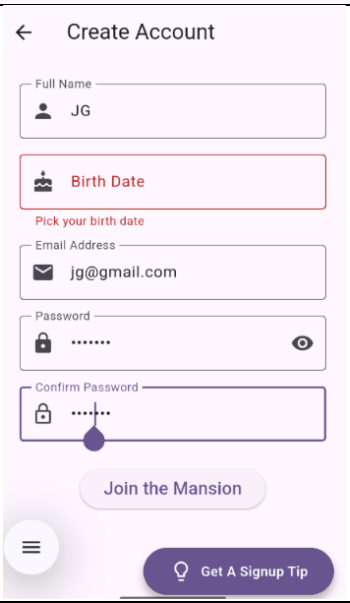

1. The Clairvoyant Ghost
   Imagine a student let an AI write the date-picker, and it shipped lastDate: DateTime(1990). Nobody notices because nobody tested. Design a five-row test table (input → expected → observed) that would have exposed this bug, run it against your picker, and report which rows your current code passes or fails — with screenshots.

input	expected	observed
August 20, 1989	pass	pass
January 1, 1991	pass	pass
January 17, 1999	pass	pass
October 5, 2003	pass	pass
September 3, 2008	pass	pass

   A picker capped at 1990 would only pass test 1, and none of the other ones. My picker is capped at 2008, so all my tests pass and look for valid (of age) birthdays.
2. The Poltergeist Field
   After rotating your emulator mid-signup, one of your three values disappears while others survive. Identify which value haunts you in your build (name? toggle? birth date?), trace exactly where each value lives in your code (controller? State field? nothing?), explain why one survives rotation and another doesn't, and propose the smallest fix.
   -

Ghost Hunt:

Test Case	**Observed results**

Empty fields + Join the Mansion → all three validators fire from Activity 10.	
Email without @, password under 6 chars → correct error under the right field.	
Eye toggle → password shows as letters, then hides again; validator still works both ways.	
Date picker → no future date selectable; empty date blocks submission.	
Back from the Lab → returns to the Foyer; typed values are gone (state died with the screen).	
From the Ballroom → system Back does not resubmit the form (pushReplacement worked).	

Double-tap Sign Up during loading → only one navigation happens (button was disabled).	
Confetti fires once on arrival; leaving and returning doesn't crash.
